

PROJECT CASE STUDY

HALAL PIZZA FUN

A multi-branch food delivery platform built around ordering, operations, payments and real-time fulfilment.

Role Full-Stack Developer (Freelancer)	Category Food Delivery	Year 2026	Primary Stack Next.js · React · TypeScript · MongoDB
---	----------------------------------	---------------------	--

Project visual shown above is the supplied Halal Pizza Fun homepage screenshot.

From a menu to a complete ordering system

Halal Pizza Fun is implemented as a multi-branch food delivery platform rather than a static restaurant website. The repository combines customer ordering with branch operations, delivery workflows, administrative controls and real-time communication. The result is a single product that covers both the public ordering journey and the internal work needed to fulfil an order.

The experience

01 • Discover The landing experience surfaces food categories, branch context and search so a customer can quickly start an order.	02 • Build Menus are branch-aware. Customers add products, adjust quantities and use configured offers or coupons.
03 • Checkout Address, delivery estimate, order totals and payment choices are brought together before the order is placed.	04 • Fulfil Order state moves through the operational system, with real-time updates and delivery-partner workflows.
05 • Engage Accounts, order history, saved addresses, reviews and notifications extend the experience beyond checkout.	06 • Operate Admin and branch teams manage menus, stock, orders, content, reports and branch configuration.

The challenge

A multi-branch business has a harder problem than simply listing food. Menus, pricing, availability, operating hours and delivery coverage can differ by branch. At the same time, customers expect a fast checkout and clear order status. The project therefore treats branch selection, order state and operational permissions as core product concerns.

The design direction

The supplied design system uses a warm food palette, strong display typography, responsive layouts, semantic tokens, rounded cards and clear interaction states. The homepage screenshot reflects that direction through a dark food-led hero, large editorial heading, prominent search, category chips and a focused call to action.

One product, several coordinated layers

The implementation separates the customer-facing Next.js application from its real-time communication process, while MongoDB provides persistence and external services extend payments, media, maps and notifications.

CUSTOMER EXPERIENCE Next.js · React 19 · Tailwind CSS Menu · Search · Checkout · Orders · Profile · Tracking	OPERATIONS Super Admin · Branch Manager · Delivery Partner Dashboards · Stock · Orders · CMS · Reports
APPLICATION / API Next.js API routes · REST endpoints · service logic · Zod validation	REAL-TIME Express + Socket.io Authenticated rooms · order events · transfer events
DATA & IDENTITY MongoDB + Mongoose NextAuth JWT + RBAC · bcryptjs	EXTERNAL SERVICES Razorpay · Cloudinary · Leaflet/Nominatim · Web Push · SMTP

High-level architecture reconstructed from the supplied repository structure.

Core implementation choices

Next.js + React	The main application foundation for routes, UI components and the customer/operations interfaces.
MongoDB + Mongoose	Persistent storage for branches, products, orders, users, reviews, coupons and supporting data.
Socket.io	Dedicated real-time process for authenticated rooms, order-state events and delivery/branch communication.
Razorpay	Online payment processing, with COD supported when enabled by configuration.
Leaflet + Nominatim	Location selection, branch discovery and delivery-related map interactions.
Cloudinary + Web Push	Media handling plus browser notifications for user and operational communication.

The product experience is built around real operations

The repository goes beyond a customer storefront. It includes the operational surfaces needed to manage a multi-branch food business, plus platform capabilities such as PWA support, validation and notifications.

Multi-branch ordering Branch-aware menus, pricing and availability make the same product work across locations.	Checkout & coupons Order totals, delivery estimation, tax handling, minimum-order rules and configured coupons are coordinated before placement.
Live order tracking Socket.io pushes order state and delivery-related events without requiring the customer to refresh the page.	Role-based operations Super Admin, Branch Manager, Delivery Partner and Customer experiences are separated by permissions and responsibilities.
Menu, stock & branch controls Operational users can manage products, stock, branch settings, timings and other configurable data.	CMS & content Homepage and supporting content can be managed without hard-coding every presentation change into the public interface.
Customer accounts Authentication, addresses, order history and product reviews continue the experience after purchase.	PWA & push Manifest/service-worker support makes the experience installable, while Web Push adds a notification channel.

The main product insight: ordering, fulfilment and administration are treated as one connected system rather than separate screens.

Security, deployment and maintainability are part of the product

The supplied repository documents security controls and a deployment model explicitly. This makes the project useful as a case study not only of interface work, but also of the engineering required to operate the service.

CSRF protection	Mutating API routes include CSRF controls.
Rate limiting	Authentication and payment endpoints use rate limiting.
Input validation	Zod is used to validate request payloads.
Password security	Passwords are hashed with bcryptjs.
Role control	RBAC separates Customer, Delivery Partner, Branch Manager and Super Admin access.
Transport hardening	The Socket.io server uses Helmet headers; secrets are expected through environment variables.

Deployment model

The documented deployment model places the Next.js application on Vercel, while the standalone Socket.io process is hosted separately on infrastructure such as Railway, Render or a VPS. MongoDB Atlas is recommended for managed database hosting. The supplied Vercel configuration targets the Mumbai region (bom1), uses a production build command and includes a scheduled monthly-report reminder route.

Project stack at a glance

Application	Next.js 16.2 · React 19.2 · TypeScript · Tailwind CSS v4
Data	MongoDB · Mongoose
Identity	NextAuth v4 · JWT · RBAC · bcryptjs
Realtime	Express 5 · Socket.io 4
Services	Razorpay · Cloudinary · Leaflet/React-Leaflet · Nominatim · Web Push · SMTP
State & Validation	Zustand · Zod · React Hook Form

Case-study takeaway

Halal Pizza Fun demonstrates how a food-delivery product becomes a real software system when branch logic, payments, real-time state, operational roles, content management and security are designed together.

Source note: project-specific claims are based on the supplied repository materials, including README.md, DESIGN_SYSTEM.md, SECURITY.md, package.json, vercel.json and application source structure. The homepage screenshot used in this case study was supplied in this conversation.
